Pooling equilibrium

- Since both types have beer, beliefs given beer are given by nature
- $EU(\text{duel} \mid \text{beer}) = 0.1 \cdot 1 + 0.9 \cdot 0$
- $EU(\text{don't} \mid \text{beer}) = 0.1 \cdot 0 + 0.9 \cdot 1$
 - Prefer not to!
- Beliefs given quiche are arbitrary
- Have to be such that P2 prefers to duel, so that P1 doesn't want to deviate from beer
- belief that player is weak given quiche is q
- $EU(\text{duel} \mid \text{quiche}) = q$
- $EU(\text{don't} \mid \text{quiche}) = 1 - q$
- If $q > 1/2$, P2 duels after observing quiche
 - No profitable deviation of P1

Separating equilibrium

- Since every info set is reached in eq, beliefs given by Bayes' law
 - If I see quiche, I know it's a weak type
 - If I see beer, I know it's a strong type
- P2 chooses optimally given these beliefs, so he fights given quiche, doesn't given beer
- Deviations don't pay for P1
 - Weak would get 0.5 instead of 1
 - Strong would get 0 instead of 3
